RE: Summertime Infectious Disease Update: West Nile Virus & Influenza

DATE: <u>June 26, 2015</u>

West Nile Virus:

West Nile Virus (WNV) first arrived in the US in New York City in 1999, and remains an important public health issue for the nation and especially for Nebraska. Since its arrival in Nebraska in 2002, Nebraska has reported a total of 3,524 persons with WNV (including 142 in 2014) placing our state's rate in the top five nationally. *Culex* species mosquitoes are competent WNV vectors and are well-established as a resident mosquito throughout our state. Since 2001, Nebraska has tracked WNV in the *Culex* mosquito population through a well-established protocol of trapping and testing mosquito pools. Each year, surveillance begins the last weekend in May and goes through the end of September. Since its inception, a total of 34,374 *Culex* mosquito pools have been tested, of which 3,247 (9.5%) were positive. For the current 2015 WNV surveillance season, one positive mosquito pool has been identified in Webster County.

Human WNV infections typically follow in the wake of positive mosquito pools, generally beginning in mid-July, peaking around Labor Day, and disappearing around mid-September. The

majority of WNV-infected persons (approximately 80%) are asymptomatic. Those who develop symptoms have an incubation period of 3-14 days. Symptoms include: fever, headache, fatigue, skin rash on the trunk of the body, swollen lymph glands, and eye pain. At the time of symptom onset, the viremia has usually resolved and the patient is seropositive for IgM antibodies. Infected persons appear to develop permanent immunity, and cannot be re-infected.

Laboratory testing:

Patients suspected of WNV infection should be tested for IgM and IgG antibodies to WNV. These tests are widely available at commercial labs. If neuroinvasive WNV is suspected, testing will be performed at the Nebraska Public Health Lab (NPHL) at our expense, provided the following criteria are met:

- The person has signs and symptoms consistent with neuroinvasive WNV disease (meningitis, encephalitis, acute flaccid paralysis, etc.).
- The specimen is accompanied by a completed NPHL requisition available here: http://dhhs.ne.gov/publichealth/Pages/puh_epi_wnv_healthpros.aspx
- The sample collection date is between June 1 and October 31.
- The submitted specimens include a CSF for WNV IgM antibody testing, and serum for WNV IgM/IgG antibody testing.
- Testing of serum specimens without a concurrent or prior CSF specimen requires preauthorization: call 402 471-2937.

WNV Test Interpretation Guidelines:

- Patients testing (+) for both IgM and IgG antibodies on an initial specimen need a "convalescent" serum (collected at least 14 days following the initial specimen).
- Stable antibody titers on acute and convalescent specimens suggest infection in the distant past. Rising IgM and IgG titers between the acute and the convalescent specimens suggest acute infection.
- Testing (+) for IgM and (-) for IgG in an acute specimen is consistent with acute WNV infection.
- Testing (+) for IgG and (-) for IgM is consistent with infection in the distant past.
- CSF which tests (+) for IgM is consistent with acute meningitis/encephalitis.

Tests	Results	Interpretation
IgM	negative	Antibody not detected = not a case of WNV
IgG	negative	
IgM	negative	Infection at undetermined time = past infection
IgG	positive	
IgM	positive	Evidence of recent or current infection
IgG	negative	
IgM	positive	Evidence of recent or current infection*; further
IgG	positive	testing necessary‡
IgM	indeterminate	Inconclusive
IgG	negative	‡request convalescent serum

^{*}Note that some individuals may have persisting antibodies from exposure during the previous WNV season.

[‡]Paired acute and convalescent serum samples may be useful for demonstration of seroconversion.

Summertime Influenza A H3N2v (related to exposure to pigs):

In 2012, public health officials reported 309 cases of H3N2v infection in 12 states. This dropped to 19 cases in 5 states in 2013 and only 3 cases in 2014. This virus is different from "human seasonal" H3N2 virus which was the predominant circulating strain during the 2014-15 influenza season. Although some adults have been infected, the majority of H3N2v cases have been in children and linked to direct or indirect exposure to pigs in the week prior to illness onset. The H3N2v cases in 2014 were epidemiologically linked to agricultural fairs, either through exhibiting pigs or walking through a swine barn. Limited, non-sustained human-to-human transmission of H3N2v virus has been noted. Some H3N2v case-patients have been hospitalized, including previously healthy people and persons with chronic underlying conditions. One death was reported in 2012 but none have been reported since. CDC guidance for clinicians regarding human infections with H3N2v is here: http://www.cdc.gov/flu/swineflu/h3n2v-clinician.htm. Other guidance documents for persons associated with fairs and schools are here: http://www.cdc.gov/flu/swineflu/h3n2v-other-guidance.htm. Please consider influenza as a diagnosis in patients with both swine exposure and influenza-like illness. For these patients, contact your local or state health department to discuss laboratory testing. This can be arranged at public health expense using the NPHL requisition for influenza testing found here: http://dhhs.ne.gov/publichealth/Documents/Influenza%20Requisition.pdf.

Table 1. Case Count: Detected U.S. Human Infections with H3N2v by State since August 2011

States Reporting H3N2v Cases	Cases in 2011	Cases in 2012	Cases in 2013	Cases in 2014
Hawaii		1		
Illinois		4	1	
Indiana	2	138	14	
lowa	3	1	1	
Maine	2			
Maryland		12		
Michigan		6	2	
Minnesota		5		
Ohio		107	1	2
Pennsylvania	3	11		
Utah		1*		
West Virginia	2	3		
Wisconsin		20		1
Total	12	309	19	3

^{*} Case in Utah occurred in April 2012.

This chart indicates the number of CDC-reported infections with H3N2v variant influenza A viruses since August 2011 and is current as of October 24, 2014. This case count will be updated each Friday as new cases are reported.

NOTE: The state totals reported by CDC may not always be consistent with those reported by state health departments. If there is a discrepancy between these two counts, data from the state health departments should be used as the most accurate number.
